

leaf_counting

December 5, 2025

1 Introduction

In this notebook, we present more experiments and results of our proposed method to identify leaves from a tree point cloud obtained by a terrestrial LiDAR scanner. We also summarize our method and discuss some drawbacks.

1.1 Approach Summary

Our method goes through several steps:

1. Keep only the tree half which faces the LiDAR scanner.
2. Cluster the tree into smaller clusters.
3. Use different clustering proposing methods (DBSCAN with different scaling of y-axis and z-axis; RANSAC plane fitting) to find the best clustering which gives the most leaf-like clusters for each smaller cluster. The leaf-like clusters are identified by shape analysis.
4. Compute leaf area for each identified leaf cluster and sum them up to get the total leaf area. The leaves areas are approximated by half the area of the convex hull of the leaf clusters, because we assume the leaves are flat surfaces.
5. Only keep the leaves which have area below 0.15 m^2 to avoid suspiciously large leaves.
6. Visualize the final result and show CT scans along different axes, for qualitative evaluation.
7. Report the total leaf area as our estimation of leaf area of the tree.

```
[1]: %matplotlib ipympl
```

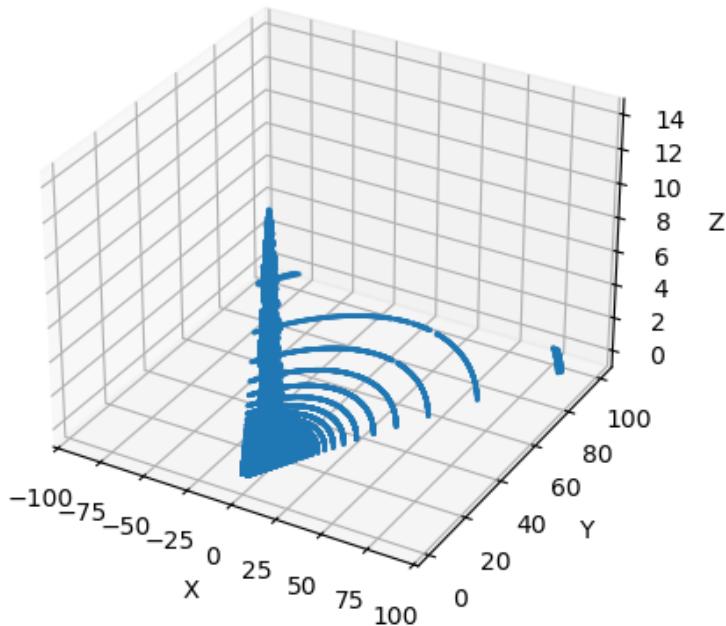

```
import numpy as np
import matplotlib.pyplot as plt
```

```
[2]: # read point clouds data from txt file, each row is a point (x,y,z)
point_clouds = np.loadtxt('tls_points.txt')
print(f"Total points in point cloud: {point_clouds.shape[0]}")
```

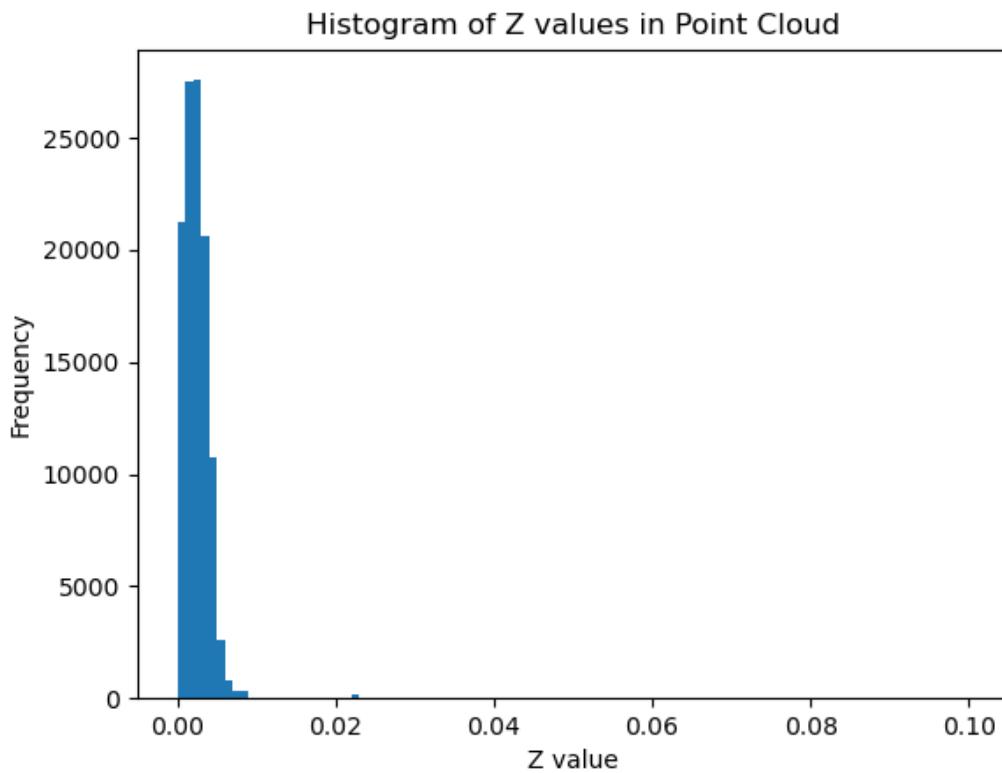

Total points in point cloud: 177748

2 Keep only the tree

```
[3]: # plot the point clouds interactively
fig = plt.figure()
ax = fig.add_subplot(111, projection='3d')
ax.scatter(point_clouds[:,0], point_clouds[:,1], point_clouds[:,2], s=1)
ax.set_xlabel('X')
ax.set_ylabel('Y')
ax.set_zlabel('Z')
plt.show()
```

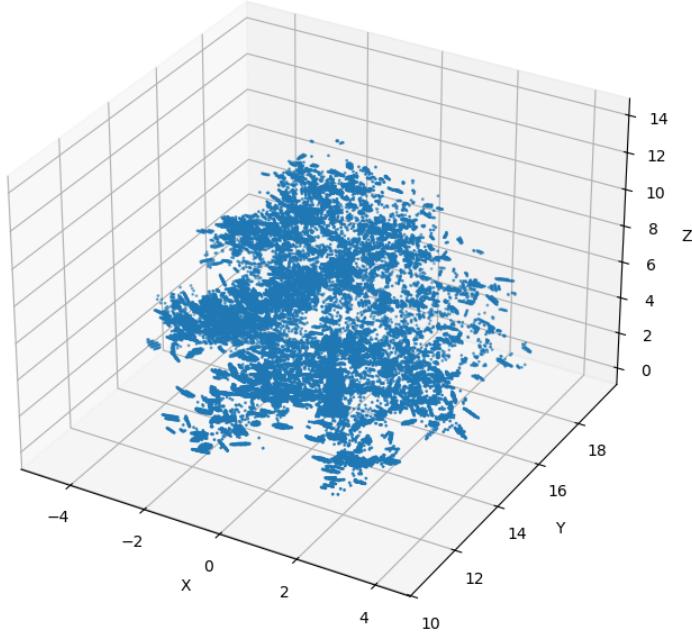

```
[4]: # remove all z points below a certain threshold (e.g., ground level)
# plot histogram of z values to determine threshold
# new plot
fig = plt.figure()
plt.hist(point_clouds[:,2], bins=100, range=(0, 0.1))
plt.xlabel('Z value')
plt.ylabel('Frequency')
plt.title('Histogram of Z values in Point Cloud')
plt.show()
```

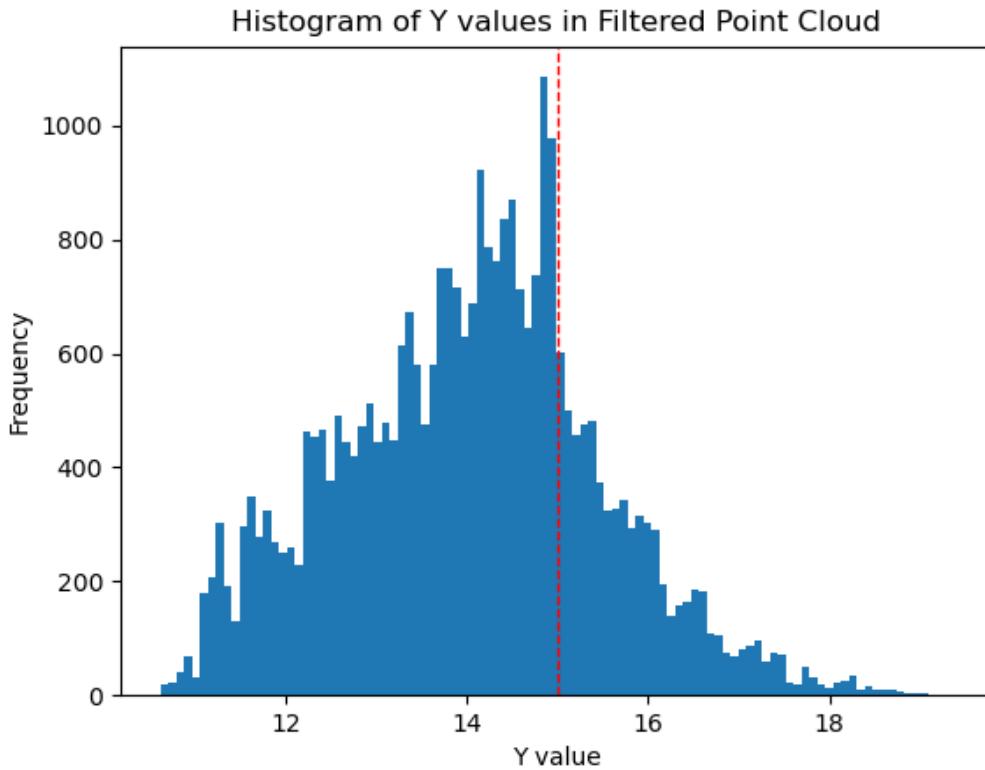

```
[5]: # remove all z_points below 0.02
z_threshold = 0.05
filtered_points = point_clouds[point_clouds[:,2] > z_threshold]
print(f"Points after removing ground level: {filtered_points.shape[0]}")
# plot filtered point clouds
fig = plt.figure(figsize=(10, 8))
ax = fig.add_subplot(111, projection='3d')
ax.scatter(filtered_points[:,0], filtered_points[:,1], filtered_points[:,2], s=1)
ax.set_xlabel('X')
ax.set_ylabel('Y')
ax.set_zlabel('Z')
plt.show()
```

Points after removing ground level: 30960

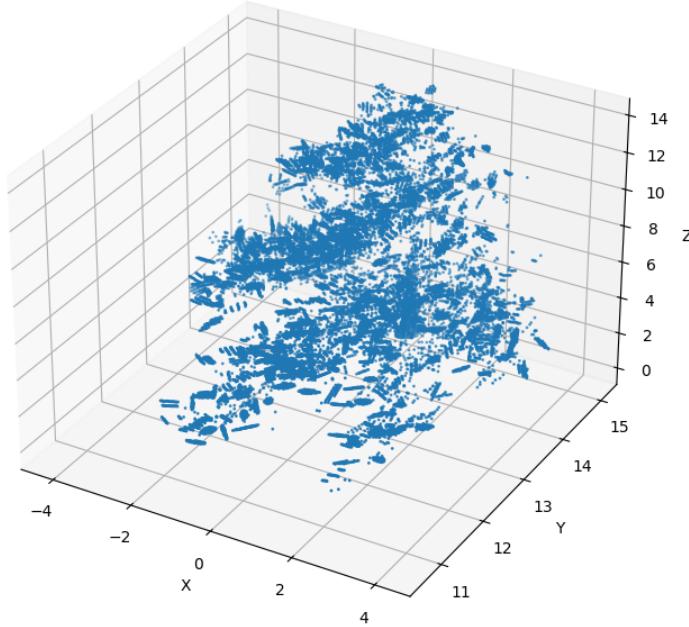

3 Keep only the tree half which faces the LiDAR scanner

```
[6]: # plot histogram on Y values
fig = plt.figure()
plt.hist(filtered_points[:,1], bins=100)
# plot mode
mode_y = 15
plt.axvline(mode_y, color='r', linestyle='dashed', linewidth=1)
plt.xlabel('Y value')
plt.ylabel('Frequency')
plt.title('Histogram of Y values in Filtered Point Cloud')
plt.show()
```

```
[7]: # filter out all points with y > mode_y
y_threshold = mode_y + 0.1 # add some margin in case some leaves get cut off
filtered_points = filtered_points[filtered_points[:,1] < y_threshold]
print(f"Points after removing high Y values: {filtered_points.shape[0]}")
# plot final point clouds
fig = plt.figure(figsize=(10, 8))
ax = fig.add_subplot(111, projection='3d')
ax.scatter(filtered_points[:,0], filtered_points[:,1], filtered_points[:,2], s=1)
ax.set_xlabel('X')
ax.set_ylabel('Y')
ax.set_zlabel('Z')
plt.show()
```

Points after removing high Y values: 24507

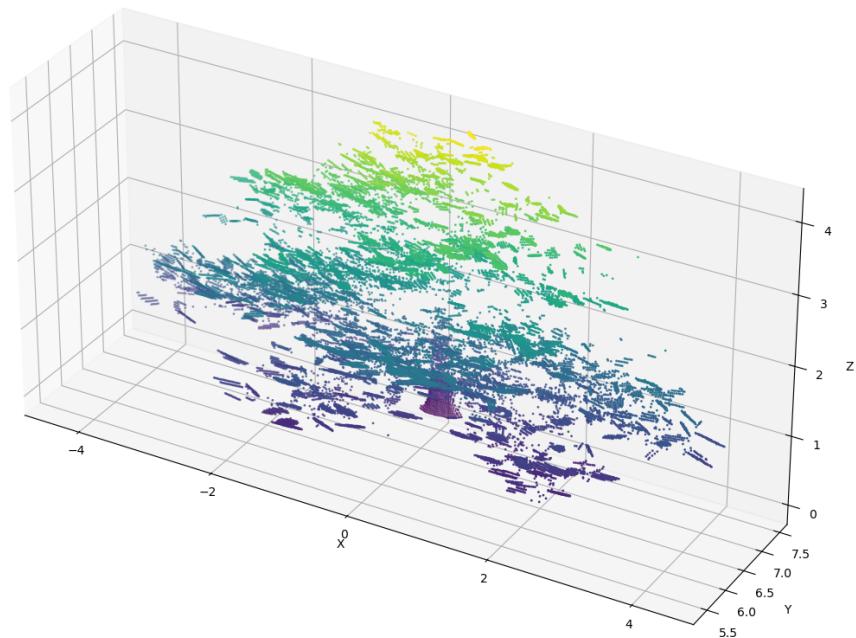

```
[8]: # down sampling the point clouds for faster processing
sample_ratio = 1 # keep 100% of points
num_points = filtered_points.shape[0]
sampled_indices = np.random.choice(num_points, size=int(num_points * sample_ratio), replace=False)
sampled_points = filtered_points[sampled_indices]

# compress the y values by 0.5 to make the point clouds denser in y direction
sampled_points[:,1] = sampled_points[:,1] * 0.5
# compress the z values by 0.7 to make the point clouds denser in z direction
sampled_points[:,2] = sampled_points[:,2] * 0.3

print(f"Points after down sampling: {sampled_points.shape[0]}")
# plot down sampled point clouds
fig = plt.figure(figsize=(13,13))
ax = fig.add_subplot(111, projection='3d')
# color by z value
sc = ax.scatter(sampled_points[:,0], sampled_points[:,1], sampled_points[:,2], c=sampled_points[:,2], cmap='viridis', s=1)
```

```
ax.set_xlabel('X')
ax.set_ylabel('Y')
ax.set_zlabel('Z')
# make all axes the same scale
ax.set_aspect('equal', adjustable='box')
# plt.colorbar(sc, ax=ax, label='Z value', shrink=0.3)
plt.show()
```

Points after down sampling: 24507

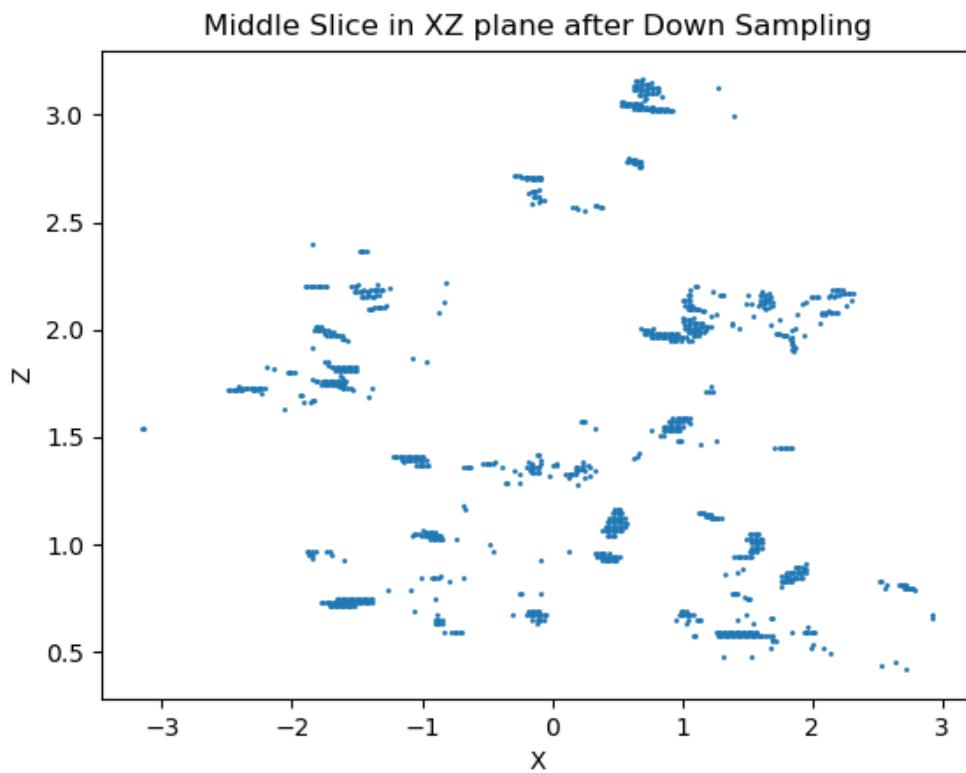

```

Slice along X axis from 3.28 to 3.78 in YZ plane

4 Finding leaf clusters

We can see that the distance between points are not uniform across the tree. It is affected by: 1. The distance from the LiDAR scanner to the leaf surface. 2. The angle between the leaf surface normal and the direction from the LiDAR scanner to the leaf surface.

DBSCAN requires a fixed distance threshold (eps) to cluster points. Therefore, we will cut the tree into smaller clusters first, then apply DBSCAN on each smaller cluster with an appropriate eps value.

4.1 Clustering the tree into smaller clusters

```
[11]: # use DBSCAN to create clusters of points (branches and leaves)
from sklearn.cluster import DBSCAN

# initial cluster
y_scale = 1
scaled_points = sampled_points.copy()
scaled_points[:,1] = scaled_points[:,1] * y_scale
eps = 0.08
dbSCAN = DBSCAN(eps=eps, min_samples=5, n_jobs=14)
```

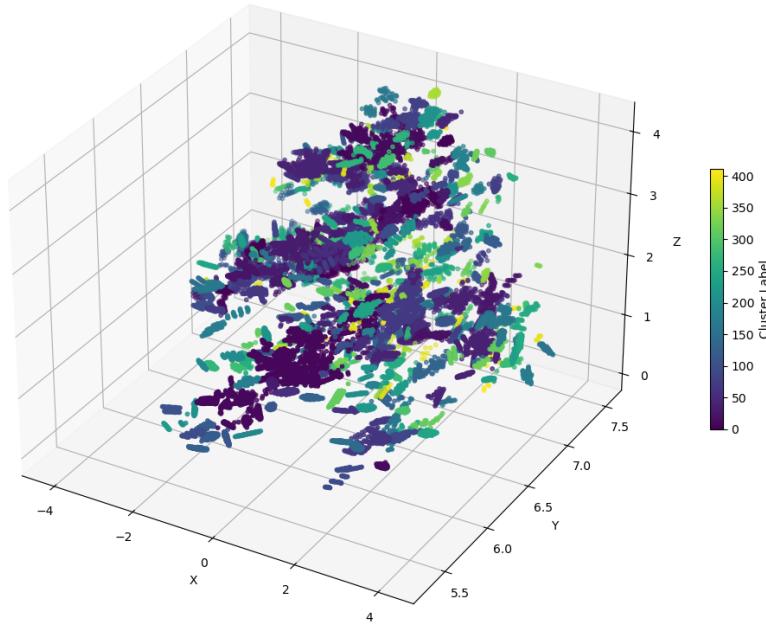

```

labels = dbSCAN.fit_predict(scaled_points)
num_clusters = len(set(labels)) - (1 if -1 in labels else 0)

# plot clusters with different colors
fig = plt.figure(figsize=(13,13))
ax = fig.add_subplot(111, projection='3d')
# remove points which belong to no cluster (label = -1)
valid_indices = labels != -1
sampled_points_plot = scaled_points[valid_indices]
labels_plot = labels[valid_indices]
sc = ax.scatter(sampled_points_plot[:,0], sampled_points_plot[:,1],  

    ↪sampled_points_plot[:,2], c=labels_plot, cmap='viridis', s=10)
ax.set_xlabel('X')
ax.set_ylabel('Y')
ax.set_zlabel('Z')
plt.colorbar(sc, ax=ax, label='Cluster Label', shrink=0.3)
plt.show()

```

4.2 For each smaller cluster, find leaf clusters using DBSCAN, RANSAC and shape analysis

```
[21]: # for each large cluster, find the best y_scale, z_scale to maximize the number
      ↴ of leaf-like clusters

from sklearn.decomposition import PCA

# analyze the shape of clusters, we want the shape that characterize leaves best
def analyze_cluster_shape(points):
    """Analyze the shape of a cluster of points using PCA."""
    if points.shape[0] < 3:

Slice along Y axis from 13.81 to 14.61 after removing large leaves

7 Summary

- We proposed a method to identify leaves from a tree point cloud obtained by a terrestrial LiDAR scanner.
- The method go through several steps:

1. Keep only the tree half which faces the LiDAR scanner.
2. Cluster the tree into smaller clusters.
3. For each smaller cluster, find the best clustering which gives the most leaf-like clusters.
The clustering proposing methods are: **DBSCAN with different scaling of y-axis and z-axis**; **RANSAC** plane fitting. The leaf-like clusters are identified by **shape analysis**.
4. We compute leaf area for each identified leaf cluster and sum them up to get the total leaf area. The leaves areas are approximated by half the **area of the convex hull** of the leaf clusters, because we assume the leaves are flat surfaces.
5. We only keep the leaves which have area below 0.15 m^2 to avoid suspiciously large leaves.
6. We visualize the final result and show CT scans along different axes, for qualitative evaluation.
7. We report the total leaf area as our estimation of leaf area of the tree.

8 Some drawbacks of our method

- If several leaves are very close to each other, such that they have high density at overlapping regions, they may be clustered as a single cluster by DBSCAN. In this case, our shape analysis may fail to identify them as leaf-like clusters. We have used RANSAC to separate such leaves, and successfully identified many leaves clusters this way. However, RANSAC does not respect the manifold structure of the point cloud, so in some cases, like the lower trunk region, where there are some nearly flat surfaces, the algorithm mistakenly identify these flat surfaces as leaves.
- We currently only identify a flat shape as leaf-like shape. However, some leaves may be curled or rolled, which may not be identified by our method. If we could identify a leaf-shape more specifically, the accuracy of leaf identification could be improved. (FAILED TO RECOGNIZE LEAF SHAPE)
- We did not solve the problem of occluded leaves. Some leaves may be partially occluded by other leaves or branches, leading to incomplete point clouds of these leaves. This may affect the shape analysis and leaf identification. Currently, we only identify the visible parts of these leaves. (FAILED TO HANDLE OCCLUSION)
